

## Steam Car Engine

- Assuming Electric Burner will heat the steam in Boiler.
- Not sure if Condenser is needed to cool the unit since the steam will be reused in the engine.
- Steam will be produced from water or a better liquid.
- This way there will be no or very little input assuming the ignition coil will increase the voltage and the electric burner will heat the water which will run the engine and the excess steam will be reintroduced in the boiler. The engine will run the alternator which will recharge the battery.
